This study analyzed participants' behavioral patterns and persistence using large-scale step count data from the Seoul Metropolitan Government's citizen health promotion initiative, Wrist Doctor 9988. As of July 2025, it analyzed participation characteristics by gender, age, and region, along with daily and weekly step patterns for approximately 2.18 million cumulative members. Analysis revealed that while women had a higher sign-up rate (63%), men had a higher average step count. Participation persistence and goal achievement rates increased with age. Step counts decreased by up to 15.7% on weekends compared to weekdays. Approximately 40% of subscribers were classified as active participants, achieving their step goals at least three times per week. Dropout analysis confirmed that users with a history of active participation had higher return rates and shorter return times. This study empirically identified participation patterns in a wearable device-based public health promotion program, providing foundational data for future program improvements and policy design.
